Stanley B. Mellsen

ABSTRACT

The effect of dust on aerodynamic drag of spheres and cylinders was calculated by using a mathematical model developed for this purpose. The results were compared to experiments previously done by other workers. The calculated and experimental results agree favourably, showing that the mathematical model is satisfactory. Impaction efficiencies and drag coefficients due to dust alone were then obtained using the model for a wide range of the inertia parameter and the results are presented graphically. The model can also be used for calculating velocity distributions and points of impact for a stream of airborne particles flowing over a sphere or cylinder.

THE IMPACTION FORCE OF AIRBORNE PARTICLES ON SPHERES AND CYLINDERS (U)

bу

Stanley B. Mellsen

1. INTRODUCTION

Extensive studies have been made of the drag exerted on spheres and transverse cylinders by moving air (Schlicting, 1960) and attempts have been made to determine the effect of introducing dust into the air stream (Gillespie and Gunter, 1957; 1959). Also, the trajectories of water drops moving in the neighborhood of a circular cylinder placed in a uniform stream of air have been calculated by numerical solution of the equations of motion (Glauert, 1940) and with a mechanical analog (Brun et al., 1953). The latter method has been used in conjunction with flight instruments used to study droplet size and distribution in icing clouds (Brun and Mergler, 1953). Measurements of aerodyn_mic drag on circular cylinders due to the blast wave from large TNT bursts have been done at DRES (Mellsen, 1974). The results of these tests have been used to provide blast loading input for structural analysis of lattice type masts also tested in the trials. On some of the trials there have been visible quantities of dust associated with the blast wave. In general the measured

strains in the masts have agreed favorably in an individual field trial with the ones predicted from theoretical analysis based upon the blast loading input from the drag data averaged over several blast trials (Laidlaw, 1977). The influence of dust is difficult to determine and generally considered negligible.

Another area of interest in connection with moving particles in an air stream is the impingement of liquid drops on protective clothing and military equipment. The impaction efficiency and force, and the droplet distribution are all of interest. The study of these effects on transverse cylinders and spheres is useful in this application.

The purpose of this report is to describe numerical solutions to the equations of motion of particles in a moving air stream, with possible applications to both the effect on aerodynamic drag from the point of view of blast loading of structures and the interaction of droplets with spheres and cylinders from a chemical defence point of view. The mathematical techniques along with their associated computer programs are described herein. Also, the results are compared with experiments done at DRES (Gillespie and Gunter, 1957).

2. DEFINITION OF THE PROBLEM

A spherical particle flowing at free stream velocity far upstream of a spherical or transverse cylindrical solid target will not necessarily follow a streamline in the vicinity of the target where the radial and axial velocity components of the fluid may be changing markedly. A particle that just impinges on the outer circumference of the target was considered. All particles of the same diameter within an envelope generated by this limiting particle trajectory would hit the target, assuming that no particles collide with other particles reflected from the target.

All particles in the steady flow field far upstream were assumed to be travelling at the velocity of the fluid but the velocities of the particles will differ from the fluid velocity as the particles approach the target. This is due to inertial effects of the particles in

the flow field near the object. The velocity of a particle immediately before contact, and also the point of contact with the target, depend upon the position of the particle within the limiting envelope far upstream from which it travels to the target. These particles all have their momentum changed when they collide with the target and in the case of solid particles are deflected in a new direction. The total change in momentum is balanced by the drag force exerted by the particles on the target.

The basic problem was, therefore, to determine the envelope of particles hitting the target and the change in particle motion due to the presence of the target in the flow. Then the drag coefficient due to particles alone could be obtained.

3. EQUATIONS OF MOTION

The motion of an individual spherical particle has been shown (Batchelor, 1967) to be determined by the following ordinary differential equations:

$$\frac{d\overline{v}_y}{dT} = \frac{C_D Re(\overline{u}_y - \overline{v}_y)}{24K}$$
 (Eq. 1)

$$\frac{d\overline{v}_{X}}{dT} = \frac{C_{D}Re(\overline{u}_{X} - \overline{v}_{X})}{24K}$$
 (Eq. 2)

where

Re = Re_o[(
$$\bar{u}_y - \bar{v}_y$$
)² + ($\bar{u}_x - \bar{v}_x$)²]³ (Eq. 3)

$$K = \frac{\sigma d^2 U}{18\mu L}$$
 particle inertia parameter (Eq. 4)

$$Re_0 = \frac{Ud\rho}{u}$$
 free stream Reynolds number (Eq. 5)

The symbols are defined in the notation section near the front of this report and the basic geometry of the flow system is illustrated in Fig. 1.

Several assumptions were inherent in the development of Eq. 1 and Eq. 2 for calculating impaction efficiency and force due to a stream of particles, including,

- (a) uniform particle distribution,
- (b) no gravitational or electrostatic forces of consequence,
- (c) monodisperse spherical particles with diameter very small in relation to the target sphere or cylinder diameter, and
- (d) free stream flow that was steady, incompressible and irrotational.

The drag coefficient is a function of Rey olds number and was available in the form of definitive empirical equations (Davies, 1945). These equations are stated as follows:

$$Re = \frac{C_D Re^2}{24} - 2.3363 \times 10^{-4} (C_D Re^2)^2 + 2.0154 \times 10^{-6} (C_D Re^2)^3 - 6.9105 \times 10^{-9} (C_D Re^2)^4$$
 (Eq. 6)

for Re < 4 or $C_DRe^2 < 140$

$$\begin{split} \log_{10} \text{Re} &= -1.29536 + 9.86 \times 10^{-1} \; (\log_{10} \text{C}_{\text{D}} \text{Re}^2) - 4.6677 \times 10^{-2} (\log_{10} \text{C}_{\text{D}} \text{Re}^2)^3 + \\ &1.1235 \times 10^{-3} \; (\log_{10} \text{C}_{\text{D}} \text{Re}^2)^3 \end{split} \tag{Eq. 7}$$
 for 3 < Re < 10^4 or $100 < \text{C}_{\text{D}} \text{Re}^2 < 4.5 \times 10^7$

4. AIR FLOW FIELD

The assumption was made that the air flow in front of the cylinder or sphere is given by classical hydrodynamics theory.

a) Cylinder

The equations of fluid velocity were derived from the stream function for ideal flow around a cylinder (Milne-Thomson, 1960). These were normalized to the free stream velocity and cylinder diameter and written as follows:

$$\ddot{u}_{x} = 1 - \frac{\ddot{x}^{2} - \ddot{y}^{2}}{\ddot{a}_{4}}$$
 (Eq. 8)

$$\vec{u}_y = 1 - \frac{\vec{x} \cdot \vec{y}}{\vec{r}^4}$$
 (Eq. 9)

b) Sphere

For purposes of comparison of the results of the theoretical work reported herein to existing experimental data the flow field about a sphere on the axis of a circular tube was applied. The flow about a sphere in the absence of the tube was then readily available from this as a limiting case.

The flow velocity was derived (Mellsen et al., 1966) from the vector potential (Smythe, 1964). The velocity components are given in terms of a series solution. For a sphere diameter of 0.8 cm and tube diameter of 2.54 cm used in the experiments (Gillespie and Gunter, 1957) sufficient accuracy (Mellsen et al., 1966) was obtained by retaining three terms of the series.

The equations were

$$\frac{u_r}{U} = -\cos \theta \left[1 - \frac{2C_0}{3} \frac{C}{r} - \frac{2A_0}{a} + \cdots \right]$$
 (Eq. 10)

$$\frac{u_{\theta}}{U} = \sin \theta \left[1 + \frac{C_0}{3} \frac{C}{r} - \frac{2A_0}{a} + \cdots \right]$$
 (Eq. 11)

The constants C_0 , C and A_0 which are dependent upon the sphere and tube diameters (Smythe, 1964) are given as follows:

$$C_0 = 1.5401075$$

C = 1.0 (normalized sphere radius)

$$A_0 = -C\left(\frac{C}{a}\right)^2 \frac{I(2)C_0}{9\pi}$$
, $I(2) = 7.5098907$

$$a = \frac{2.54}{0.8}$$
 C (normalized tube radius)

 $u_{\rm e}$ and $u_{\rm r}$ are shown in Fig. 2.

Converting to rectangular co-ordinates gives

$$\bar{u}_{x} = -\frac{u_{r}}{U}\cos\Theta + \frac{u_{\theta}}{U}\sin\Theta$$
 (Eq. 12)

$$\bar{u}_y = \frac{u_r}{u} \sin \Theta + \frac{u_\theta}{u} \cos \Theta$$
 (Eq. 13)

The equation for flow around a sphere in the absence of the tube is given by letting the value of "a" approach infinity.

For
$$a \rightarrow \infty$$
, $C_0 \rightarrow 1.5$ (Smythe, 1964)

Eq. 10 becomes $\frac{u_r}{U} = -\cos \Theta \left[1 - \left(\frac{L}{r}\right)^3\right]$ (Eq. 14)

Eq. 11 becomes $\frac{u_\theta}{U} = \sin \Theta \left[1 + \frac{1}{2}\left(\frac{L}{r}\right)^3\right]$ (Eq. 15)

Eqs. 14 and 15 are well known in ideal flow theory (Batchelor, 1967) and therefore serve as a partial check on the correctness of Eqs. 10 and 11.

5. VELOCITY CHANGE OF AN INDIVIDUAL PARTICLE

To calculate the drag force due to airborne particles, the velocity change of an individual particle due to the presence of the cylinder or sphere in the flow was first considered. The velocity change determined applied to both the cylindrical and spherical targets because the same geometry could be used for both (Fig. 3).

The motion considered concerned a spherical particle which starts far upstream within the envelope of particles which travel to the target, eventually hit it and are reflected by it in a new direction. The total change in direction of a particle which comes from a far upstream offaxis position y, and hits the target at a point defined by y' (Fig. 3), is represented by γ . For a spherical particle the angle of incidence, α , is equal to the angle of reflection. Then

$$\gamma = \left(\frac{\pi}{2} - \Theta\right) + \alpha$$
 (Eq. 16)

where

$$0 = \sin^{-1}\left(\frac{y'}{L}\right) = \tan^{-1}\left(\frac{y'}{\sqrt{L^2 - (y')^2}}\right) \quad (Eq. 17)$$

and
$$\alpha + \beta = \frac{\pi}{2} - \Theta$$
 (Eq. 18)
where $\beta = \tan^{-1} \left(\frac{v_y}{v_x} \right)$

and v_x and v_y are the components of particle velocity just before impact with the target. Substituting the value of α obtained from Eq. 18 into Eq. 16 gives

$$\gamma = \pi - 2\theta - \beta$$
 (Eq. 20)

Substituting Eqs. 17 and 19 into Eq. 20 gives an equation of γ suitable for computation. Thus:

$$\gamma = \pi - 2 \tan^{-1} \left(\frac{y^1}{\sqrt{1 - y^{12}}} \right) - \tan^{-1} \left(\frac{v_y}{v_x} \right) \quad (Eq. 21)$$

or in non-dimensional terms

$$\gamma = \pi - 2 \tan^{-1} \left(\frac{\bar{y}^{i}}{\sqrt{1 - \bar{y}^{i}^{2}}} \right) - \tan^{-1} \left(\frac{\bar{v}_{y}}{\bar{v}_{x}} \right) \quad (Eq. 21a)$$

The component of velocity in the direction of free field flow immediately after particle reflection is

$$v_y' = v \cos \gamma$$
 (Eq. 22)

where
$$v = \sqrt{v_{\chi}^2 + v_{y}^2}$$
 (Eq. 23)

or in non-dimensional terms
$$\vec{v}_{\chi}' = \vec{v} \cos \gamma$$
 (Eq. 22a)

and
$$\tilde{v} = \sqrt{\tilde{v}_x^2 + \tilde{v}_y^2}$$
 (Eq. 23a)

The total change of the component of velocity in the direction of free stream flow due to reflection from the target is then given by the following relationship:

$$\Delta v_{x} = v_{x} - v \cos \gamma \qquad (Eq. 24)$$

6. THE DRAG FORCE DUE TO PARTICLES ALONE

The force $\mathbf{F}_{\mathbf{p}}$ of a stream of particles hitting a cylinder or sphere is related to the change in momentum which in general is given by the following relationship:

$$F_{D} = m' \Delta v_{x}$$
 (Eq. 25)

where m' is the total mass of particles having its momentum changed per unit time and Δv_{χ} is its change of velocity in the free stream flow direction.

The quantity m' can be calculated using the following equation: $m' = \rho_D A_d V_{XO}$ (Eq. 26)

where ρ_p is the uniform particle density per unit volume of air far upstream, A_d is the far upstream cross sectional area of the envelope of particles which eventually hits the sphere or cylinder, and $v_{\chi O}$ is the far upstream particle velocity which is assumed equal to the fluid velocity. Combining Eqs. 25 and 26 gives

$$F = \rho_p A_d v_{x0} \Delta v_x \qquad (Eq. 27)$$

 Δv_{χ} was not constant but was shown in the previous section to be a function of the off-axis, upstream starting location of an individual particle. This can be accounted for by integrating the velocity change over the range of starting locations across the particle envelope. Then the equation of force becomes

$$F = \rho_p v_{x0} \int_0^A \Delta v_x dA \qquad (Eq. 28)$$

where dA is an element of cross sectional area at location y.

Assuming that the particles do not interact with each other, the equation of drag force due to particles alone is then obtained in usable form by substituting Eq. 24 into Eq. 28 which gives the following equation:

$$F_{p} = \rho_{p} v_{xo} \int_{0}^{A_{q}} (v_{x} - v \cos \gamma) dA \qquad (Eq. 29)$$

7. THE DRAG COEFFICIENT

(a) Cylinder

For a transverse cylinder of unit length, Eq. 29 becomes

The land of the state of the st

$$F_{s} = 2\rho_{p} v_{xo} \int_{0}^{y_{c}} (v_{x} - v \cos \gamma) dy$$
 (Eq. 30)

In non-dimensional terms this is written

$$\frac{F_{s}}{\rho_{p}U^{2}L} = 2\bar{v}_{xo} \int_{0}^{\bar{y}_{d}} (\bar{v}_{x} - \bar{v} \cos \gamma) d\bar{y}$$
 (Eq. 31)

The drag coefficient is defined as follows:

$$c_{D} = \frac{p}{k_{SD} U^{2}}$$
 (Eq. 32)

where p is the average drag pressure (Schlicting, 1960).

The average drag pressure for a cylinder of unit length is given by the following equation:

$$p_{c} = \frac{F}{2L}$$
 (Eq. 33)

Substituting Eq. 33 into Eq. 32 and the resulting equation into Eq. 32 gives π

$$C_{DC} = 2\bar{v}_{x0} \int_{0}^{\bar{y}_{d}} (\bar{v}_{x} - \bar{v} \cos \gamma) d\bar{y}$$
 (Eq. 34)

b) Sphere

For a sphere Eq. 29 becomes

$$F_{s} = 2\pi \rho_{o} v_{xo} \int_{0}^{y_{c}} (v_{x} - v \cos \gamma) y dy$$
 (Eq. 35)

In non-dimensional terms this is written

$$\frac{F_{s}}{\rho_{p}U^{2}L^{2}} = 2\pi \bar{v}_{xo} \int_{0}^{\bar{y}} (\bar{v}_{x} - \bar{v} \cos \gamma) \bar{y} d\bar{y}$$
 (Eq. 36)

The drag pressure on the sphere is given by

$$p_s = \frac{F_s}{\pi L^2}$$
 (Eq. 37)

Substituting Eq. 36 into Eq. 37 and the resulting equation into Eq. 32 gives the drag coefficient for a sphere as follows:

$$C_{DS} = 4\bar{v}_{XO} \int_{0}^{\bar{v}_{d}} (\bar{v}_{X} - \bar{v}' \cos \gamma) \bar{y} d\bar{y} \qquad (Eq. 38)$$

8. <u>INTEGRATION METHOD FOR THE DRAG COEFFICIENT EQUATIONS</u>

a) Cylinder

Let
$$f(\bar{y}) = \bar{v}_y - \bar{v} \cos \gamma$$
 (Eq. 39)

Then Eq. 33 can be written

$$C_{D} = 2\bar{v}_{xo} \int_{0}^{\bar{y}_{d}} f(\bar{y}) d\bar{y}$$
 (Eq. 40)

 $\int\limits_0^{\bar{y}_d} f(\bar{y}) \ d\bar{y} \ was \ integrated \ numerically \ by \ dividing \ the \ upstream$

cross sectional area into strips of equal width Δy , and calculating the contribution from each strip. These contributions were then summed as follows:

$$\int_{0}^{\bar{y}_{d}} f(\bar{y}) d\bar{y} = \frac{f(\bar{y}_{1}) + f(\bar{y}_{n})}{2} + \sum_{i=2}^{i=n-1} f(\bar{y}_{1}) \Delta \bar{y}$$
 (Eq. 41)

where y_i increases with i from $\bar{y}' = 0$ to $\bar{y}_n = \bar{y}_d$.

b) Sphere

Using Eq. 39 in Eq. 38 gives the following equation for the drag coefficient of a sphere

$$C_{Ds} = 4\bar{v}_{XO} \int_{O} f(\bar{y}) \ \bar{y} \ d\bar{y}$$
 (Eq. 42)

A CONTROL OF THE CONT

$$\int\limits_0^{\bar y} f(\bar y) \ \bar y \ d\bar y \ was \ integrated \ numerically \ by \ dividing \ the \ upstream$$

cross sectional area into concentric annuli of equal width $\Delta \bar{y}$ and calculating the contribution from each ring. These contributions were then summed as follows:

$$\int_{0}^{\bar{y}_{d}} f(\bar{y}) d\bar{y} = \sum_{i=1}^{n} i f(\bar{y}_{i}) \bar{y}_{i} \Delta \bar{y}$$
 (Eq. 43)

where y_i increases with i from $\bar{y}_i = \Delta \bar{y}$ to $\bar{y}_n = \bar{y}_d$

9. SOLUTION OF THE DRAG COEFFICIENT EQUATIONS

To solve Eq. 34 or Eq. 38 for the drag coefficient it was necessary to know the values of \vec{v}_x , \vec{v}' and γ in the range $0 \le \vec{y} \le \vec{y}_d$.

The first step was to find the value of $\bar{\mathbf{y}}_{d}$ which was the upper limit of the integral. This was done by an iterative procedure called the half interval method (Carnahan et al., 1969). The value of $\bar{\mathbf{y}}$ for the critical particle was estimated far upstream and the path followed to the target. The difference between the ordinate of the target path and the ordinate of the point on the actual path parallel to the tangent path was the miss criterion used. The direction of the tangent path was not known a priori but was assumed parallel to the actual path. The half interval method previously mentioned was applied to determine a better initial estimate. Then the path was followed to the target again for another calculation of miss distance. This process was repeated several times until sufficient accuracy was achieved. The plane of initial position of particles which was perpendicular to the flow direction was located far enough from the target so that free stream conditions prevailed. A distance of five target radii upstream of the target centre was considered adequate (Batchelor, 1967).

The path of an individual particle was determined step by step by applying a fourth order Runge-Kutta method (Carnahan et al., 1969) to

the equations of motion (Eqs. 1 and 2). The values of Re and K in these equations were easily determined for each new step by direct substitution of previously determined values into Eqs. 3, 4 and 5, but the value of C_D Re in Eqs. 1 and 2 had to be calculated in each step by numerical solution of the definitive empirical equations (Eqs. 6 and 7). This was done using Newton's Method (Carnahan et al., 1969) for finding the zeros of a function. The values of \bar{u}_{χ} and \bar{v}_{y} in Eqs. 1, 2 and 3 were calculated from Eqs. 8 and 9 for a cylindrical target and Eqs. 10, 11, 12 and 13 for a spherical target.

Once the value of \bar{y}_d had been determined the integration procedures described in Section 8 of this report were applied. The values of $f(\bar{y}_i)$ used in Eqs. 41 and 43 were obtained from Eq. 39. The quantities \bar{v} and γ used in the latter equation were calculated from Eqs. 23a and 21a respectively. The values of \bar{v}_x , \bar{v}_y and \bar{y}' used in the latter two equations were calculated by following a particle from its initial position to the cylindrical or spherical target using the previously described step by step procedure applied in determining the value of \bar{y}_d .

10. IMPACTION EFFICIENCY

The impaction efficiency was defined as the ratio of the cross sectional area of the far upstream envelope of particles which eventually hit the target to the cross sectional area of the target itself. For a transverse cylindrical target this is simply given by the value of \bar{y}_d . For a spherical target it is given by \bar{y}_d^2 .

11. COMPUTER PROGRAMS

Computer programs were written in Fortran IV for the DRES IBM 1130 computer to obtain solutions to the drag coefficient equations by the method described in Section 9 of this report. The complete programs, together with one set of results for each, are shown in Appendix A for the cylinder in free space and in Appendix B for the sphere in a tube or in free space (Appendix B). These programs are annotated so that the

functions of their various parts can be understood without further description. The application of the method described in Section 9, which was used in the programs, is straight forward with the exception of the step by step integration procedure near the target sphere or cylinder. This procedure is therefore explained as follows.

The particle motion was calculated in time steps, ΔT , until the particle was just one time step away from the target. Then the time increment size was decreased by a factor of ten and step by step integration continued until the particle was one new time step away from the target. At this point the time increment size was decreased by another factor of ten and the integration allowed to proceed until the target was reached. This method ensured that the position of the target and particle coincided within a maximum error given by the distance travelled during one percent of the original time step size, while allowing the particle to reach the proximity of the target in an adequate but small number of steps.

12. RESULTS

Drag coefficients and impaction efficiencies were calculated by means of the computer programs (Appendix A and B) from two main points of view. First, they were calculated using the particle sizes, fluid velocities and target configurations used in experiments done at Suffield many years ago (Gillespie and Gunter, 1957; 1959). This was done so that a comparison of the results from the theoretical calculation of drag due to particles in air could be made with existing information obtained from experiments. The results were obtained for a narrow range of particle sizes and fluid velocities and, correspondingly, a narrow range of inertia parameters and free stream particle Reynolds numbers. Next, calculations of impaction efficiencies and drag coefficients were done for a wide range of inertia parameters. The impaction efficiencies were compared with the results of other workers (Friedlander, 1977) but no results were available for comparison to the calculated drag coefficients over this

wide range of the inertia parameter. All the results previously mentioned are shown in Tables 1 and 2 and Fig. 4 - Fig. 9, along with plots of the calculated distribution of forces due to elastic reflection of particles from a cylinder (Fig. 10) and a sphere (Fig. 11). The latter two figures were plotted from the sample computer results shown with their corresponding programs in Appendix A and B. Further details explaining the significance of the tables and figures are described as follows.

The calculated results for the various particle sizes and fluid velocities used in the experiments done at Suffield (Gillespie and Gunter, 1957; 1959) are shown for a cylinder (Table 1) and for a sphere (Table 2). The sizes of these two targets also correspond to those in the experiments. The calculations were done for a 0.2 centimetre diameter cylinder in free space and a 0.8 centimetre sphere in a 2.54 centimetre tube. The tube which was used in all the experiments was included for the sphere since the velocity potential was readily available (Smythe, 1964). However, the effect of the presence of the tube on the potential flow and the final theoretical results was found to be negligible. Similarily, the effect of not including the tube in the potential flow for the cylinder is expected to be negligible.

A reason for tabulating the calculated results is to show clearly that the effect of particle size on the calculated drag coefficient for the sizes used in the experiments was negligibly small. This conclusion was also drawn from the experiments reported by Gillespie and Gunter (1957; 1959). The drag coefficients due to the middle size particles alone were plotted against target Reynolds number for the cylinder (Fig. 4) and for the sphere (Fig. 5). Also shown for the purpose of comparison of experiment to theory, described in the following section, are the drag coefficients due to air alone.

The impaction efficiencies for a wide range of the inertia parameter were plotted for cylinders (Fig. 6) and for spheres (Fig. 8). The cylinder results were plotted for $\phi = 1000$. The definition of ϕ

and the reason for its value choice are described as follows. The collection efficiency and also the drag coefficient are a function of two dimensionless groups, the inertial parameter, K, and the free stream particle Reynolds number, Re_O. A new dimensionless group

$$\phi = \frac{\text{Re}_0^2}{K}$$
 (Eq. 44)

independent of particle size was introduced. According to the rules of dimensionless analysis this is permissible, but the efficiency is still determined by two groups which for convenience were chosen to be K and ϕ . The collection efficiencies were calculated by means of a mechanical analog and plotted for values of ϕ by other workers (Brun et al., 1953). The results for the middle value of ϕ from this work are also shown (Fig. 6) for comparison. The sphere results were plotted (Fig. 8) for an Reovalue of 128. Again this choice was made for convenience of comparison to other work. The choice was the middle value of seven for which curves calculated from inviscid flow theory by Dorsch, Saper and Kadow are shown (Friedlander, 1977). The curve is also shown in Fig. 8.

The calculated drag coefficient due to particles alone were plotted for a wide range of inertia parameters for cylinders (Fig. 7) and for spheres (Fig. 9). In these two figures each curve was fitted by eye through several data points obtained by applying the computer programs (Appendix A and B) to various particle diameters for the cylinder case and various target diameters for the sphere case.

10. COMPARISON OF THEORETICAL RESULTS TO EXPERIMENTAL DATA

The experimental work previously done at Suffield (Gillespie and Gunter, 1957; 1959) indicated that the drag force of a sphere or cylinder is given by the following equation:

$$F = 1/2\rho * U^2 C_{D_e}^A$$
 (Eq. 45)

where
$$\rho^* = \rho + \rho_D$$
 (Eq. 46)

and generally ρ and ρ_p are unequal. For Eq. 45 to be true, the drag coefficients due to particles alone carried by air and due to air alone must be equal. This is shown as follows. The total drag force consisted of two parts expressed by the following equation:

$$F_p + F_a = 1/2\rho_p U^2 A C_{Dp} + 1/2\rho U^2 A C_D$$
 (Eq. 47)

Comparison of Eq. 45 and 46 to Eq. 47 shows that

$$(\rho + \rho_p)C_{De} = \rho_pC_{Dp} + \rho C_D$$
 (Eq. 48)

 \mathbf{C}_{Dp} and \mathbf{C}_{D} must be equal for Eq. 48 to be true.

The results obtained herein (Tables 1 and 2) and illustrated in Fig. 4 and 5 show that the calculated drag coefficients due to particles carried by air are considerably greater than the established drag coefficients due to air alone (Schlicting, 1960). The discrepancies between the experimental and calculated drag coefficients were accounted for by showing that the velocity of the particles in the experiments were considerably lower than the mean air velocity.

The particles which were introduced by Gillespie and Gunter into the air stream with zero velocity in the direction of air flow were accelerated along a horizontal section of 2.54 cm tube, 17 cm long, and a vertical section, 78 cm long, giving a total tube length of 95 cm between the starting point and the test section. Calculations of velocity as a function of distance for particles accelerated from rest were done to simulate Gillespie's experiments (Mellsen, in draft). The results for a travelled distance of 95 cm for the various mean air velocities and number median diameter used in the experiments are shown in Table 3. Also, the curves of velocity versus distance for the three diameters and one air velocity are illustrated in Fig. 14.

The particle velocities were difficult to calculate because the behavior of the particles travelling in the air stream around the corner in the tube was very complex. The velocity of the air in a straight cross section of the tube was zero at the walls and increased to the centre to 1.22 to 1.25 times the mean velocity (Prandtl and Tietjens,

1957). Therefore, the particle velocities were affected by the location of the particles in the tube cross section. This could not be accounted for because the time history of the location of the particles was not known. As a simplifying approximation, the mean air velocity was assumed to act on the particles over their length of travel in the tube which was also assumed vertical over its entire length. The experimental results indicate that the variation in velocities was less than this method of calculation shows. A mean value of drag force due to the presence of all particle sizes was used to offset this.

The drag coefficients which were calculated for particles with a free stream velocity equal to the mean air velocity (Table 1 and 2) were then adjusted to simulate the special conditions of the experiments as follows. The drag coefficients in the experiments were based on the mean air velocities as measured by a rotameter. The drag coefficients due to the particles travelling at lower velocities were adjusted to the mean air velocity by the following relationship for flow over the cylinder.

$$C_{DpU} = C_{Dc} \left(\frac{v_{rms}}{U} \right)^2$$
 (Eq. 49)

This method was justified because, for the purpose of comparison, the calculated drag coefficients over the range of velocities and particle sizes used were sufficiently near a constant value (Table 1). All three particle sizes were assumed present in equal quantities in the air flow. Then, since the drag forces vary as the square of the velocity, the root mean square particle velocity, $v_{\rm rms}$, was calculated for each mean fluid velocity (Table 3) and used in Eq. 49 to obtain a value for the drag coefficient due to dust alone at each mean air velocity (Table 4). The overall drag coefficients due to air and particles were then calculated for the dust concentrations used in the experiments, namely 2 and 5 kilograms per cubic metre of space. This was done by solving Eq. 48 for $C_{\rm De}$. That is

$$C_{De} = \frac{\rho_p C_{Dc} + \rho C_D}{\rho + \rho_p}$$
 (Eq. 50)

The results are shown for each mean air velocity (Table 4) and plotted along with the drag coefficient for air alone (Fig. 12) as was done for the experiments of Gillespie and Gunter (1957; 1959).

A similar method was used to obtain the overall drag coefficients for the sphere with the exception that, as for the experimental results, they were corrected for the presence of the tube walls by the Landenburg correction (Gillespie and Gunter, 1957). That is, the drag coefficients due to particles alone were divided by the factor 1 + 2.4 L/a to obtain the corrected drag coefficient, $C_{\rm DL}$. For the sphere and tube radii used, the factor is 1.756. Then, the overall drag coefficient for the sphere was obtained from

$$C_{De} = \frac{\rho_p C_{DL} + \rho C_D}{\rho + \rho_p}$$
 (Eq. 51)

The results are shown for each mean air velocity in Table 4, and plotted along with the drag coefficient for air alone in Fig. 13.

14. DISCUSSION

The equations of motion (Eq. 1 and 2) have never been proven experimentally (Friedlander, 1977) although they have been used to calculate deposition efficiencies for cylinders (Glauert, 1940). The mathematical model described herein used these equations to calculate collection efficiencies for cylinders which compare favorably (Fig. 6) with the results obtained using a differential analyzer (Brun et al., 1953). Also, the impaction efficiencies for spheres (Fig. 8) agree with solutions to the equations obtained by other workers (Friedlander, 1977).

In the work reported herein, the mathematical model for calculating impaction efficiency was extended to obtain the impaction forces due to particles in air flowing over spheres and cylinders. These results agree favorably with experiments previously done at Suffield (Gillespie and Gunter, 1957) when adjusted to the special conditions of the experiment. The experiments do support the theory, but the theoretical results

show that the results of the experiments are not applicable to the free field case of drag due to dusty air flowing over a cylinder or sphere.

The model could also be extended to blast loading problems. Since the effect of compressibility becomes important in these problems it would have to be accounted for. This could be done in the mathematical model by changing the air flow field equations to include it. The model could also be used to calculate the actual distributions of impaction velocities on cylinders (Fig. 10) and spheres (Fig. 11) in special cases which may have applications in chemical and nuclear defence.

15. CONCLUSIONS

A mathematical model was developed for calculating the impaction forces due to airborne particles on spheres and cylinders. The model can also be used for calculating impaction efficiences, velocity distributions, and points of impact for a stream of airborne particles flowing over a sphere or cylinder. Hence, the drag coefficient for the particles on the sphere or cylinder can be determined.

INSTRUCTIONS

- ORIGINATING ACTIVITY: Enter the name and address of the organization issuing the document.
- 2a. DOCUMENT SECURITY CLASSIFICATION: Enter the overall security classification of the document including special warning terms whenever applicable.
- 2b GROUP Enter security reclassification group number. The three groups are defined in Appendix 'M' of the DRB Security Regulations.
- DOCUMENT TITLE: Enter the complete document title in all capital letters. Titles in all cases should be unclassified. If a sufficiently descriptive title cannot be selected without classification, show title classification with the usual one-capital-letter abbreviation in parentheas immediately following the title.
- 4 DESCRIPTIVE NOTES: Enter the category of document, e.g. technical report, technical note or technical letter. If appropriate, enter the type of document, e.g. interim, progress, summary, unnuel or final. Give the inclusive dates when a specific reporting period is covered.
- AUTHOR(S): Enter the name(s) of author(s) as shown on or in the document. Enter last name, first name, middle initial.
 If initiary, show rank. The name of the principal author is an absolute minimum requirement.
- DOCUMENT DATE. Enter the date (month, year) of Establishment approval for publication of the document.
- 7n TOTAL NUMBER OF PAGES: The total page count should tollow normal pagination procedures, i.e., enter the number of pages containing information.
- 7). NUMBER OF REFERENCES: Enter the total number of orderences cited in the document.
- 8a PROJECT OR GRANT NUMBER: If appropriate, enter the applicable research and development project or grant number under which the document was written.
- 86 CONTRACT NUMBER It appropriate, enter the applicable manber under which the document was written.
- ORIGINATOR'S DOCUMENT NUMBER(S): Enter the official document without by which the document will be identified and controlled by the originating activity. This comber must be unique to this document.

- 9b. OTHER DOCUMENT NUMBER(S): If the document has been assigned any other document numbers (either by the originator or by the sponsor), also enter this number(s).
- 10. DISTRIBUTION STATEMENT: Enter any limitations on further dissemination of the document, other than those imposed by security classification, using standard statements such as:
 - "Qualified requesters may obtain copies of this document from their defence documentation center."
 - (2) "Announcement and dissemination of this document is not authorized without prior approval from originating activity,"
- SUPPLEMENTARY NOTES: Use for additional explanatory notes.
- SPONSORING ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring the research and development. Include address.
- 13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document, even though it may also appear elsewhere in the body of the document itself. It is highly desirable that the abstract of classified documents be unclassified. Each peragraph of the abstract shall end with an indication of the security classification of the information in the paregraph (unless the document itself is unclassified) represented as (TS), (S), (C), (R), or (U).

The length of the abstract should be limited to 20 single-spaced standard typewritten lines; 7½ inches long.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a document and could be helpful in cataloging the document. Key words should be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context.
